

Clinical Study on the Efficacy of Low-dose Aspirin in Preventing Cardiovascular Events

Abstract

Objective: To evaluate the efficacy and safety of low-dose aspirin in the primary prevention of cardiovascular events in patients with type 2 diabetes mellitus.

Methods: A randomized controlled trial was conducted from January 2023 to December 2024. A total of 500 patients with type 2 diabetes were enrolled and randomly assigned to either the aspirin group (100mg daily) or the placebo group. Primary endpoints included major adverse cardiovascular events (MACE).

Results: The incidence of MACE was significantly lower in the aspirin group compared to the placebo group (8.2% vs 12.6%, $p=0.03$). No significant difference in major bleeding events was observed between the two groups.

Conclusion: Low-dose aspirin is effective in reducing cardiovascular events in patients with type 2 diabetes, with an acceptable safety profile.
